(54) Photodiode active pixel sensor with shared reset signal and row select

(57) An active pixel sensor having a plurality of pixels arranged in rows and columns that are read out of the active pixel sensor in a sequential order of rows with each of the pixels having a photodiode as the photo-detector element. The row that is currently being read has an amplifier within each of the pixels in that row operatively connected to a column signal bus by a reset transistor configuration. A floating diffusion within each pixel is operatively connected to the reset transistor within the pixel such that the reset gate on the reset transistor for the row of photodetectors that is currently being read is also connected to the drain of the next row of pixels to be read resulting in a configuration that allows selection and deselection of rows via the reset busses. During selection of a particular row the amplifiers within each pixel of that row are operatively connected to the column signal bus while the amplifiers of the remaining rows are deselected and not connected to the column signal bus.

Description

FIELD OF THE INVENTION

[0001] This invention relates to the field of solid state photo-sensors and imagers referred to as Active Pixel Sensors (APS) that have active circuit elements associated with each pixel, and more specifically to Solid State Imagers that employ photodiode type photo-detectors 4 transistor pixels and correlated double sampling (CDS).

BACKGROUND OF THE INVENTION

[0002] APS are solid state imagers wherein each pixel contains the typical solid state pixel elements including a photo-sensing means, reset means, a charge to voltage conversion means, and additionally all or part of an amplifier. The photocharge collected within the pixel is converted to a corresponding voltage or current within the pixel as discussed in prior art documents such as "Active Pixel Sensors: Are CCD's Dinosaurs?", SPIE Vol. 1900-08-6194-1133 July 1993, by Eric Fossum. APS devices have been operated in a manner where each line or row of the imager is selected and then read out using a column select signal as discussed by E. Fossum in "Active Pixel Sensors: Are CCD's Dinosaurs?", SPIE Vol. 1900-08-6194-1133 July 1993 and by R. H. Nixon, S. E. Kemeny, C. O. Stoller, and E. R. Fossum, In "128 x128 CMOS Photodiode-type Active Pixel Sensor with On-chip Timing, Control and Signal Chain Electronics". Proceedings of the SPIE vol. 2415, Charge-Coupled Devices and Solid-State Optical Sensors V, paper 34 (1995). The selection of rows and columns within an Active Pixel Sensor is analogous to the selection of words and bits in memory devices. Here, the selection of an entire row would be analogous to selecting a word and the reading out of one of the columns of the Active Pixel Sensor would be analogous to selecting or enabling a single bit line within that word. Conventional prior art photodiode devices teach architectures employing 4 transistor designs, where the 4 transistors (4T) are typically the Transfer, Row Select, Reset, and Source Follower Amplifier transistors. While this architecture provides the advantages of yielding APS devices having the capability to easily perform CDS and provide low readout noise, these 4T pixels suffer from low fill factor. Fill factor is the percentage of pixel area that is devoted to the photosensor. Since these 4 transistors and their associated contact regions and signal busses are placed in each pixel, and since contact regions typically consume a large amount of pixel area due to the required overlap and spacings of various layers, the fill factor for the pixel is reduced because of the large area consumed that could otherwise be used for the photodetector. Connection to each of these components to the appropriate timing signal is done by metal busses that traverse the entire row of pix-

els. These metal busses are optically opaque and can occlude regions of the photodetector in order to fit them into the pixel pitch. This also reduces the fill factor of the pixel. Decreasing the fill factor reduces the sensitivity and saturation signal of the sensor. This adversely affects the photographic speed and dynamic range of the sensor, performance measures that are critical to obtaining good image quality.

[0003] Prior art devices employing 3 transistor (3T) based pixels have a higher fill factor than 4T pixels, but these 3T pixels cannot easily perform CDS. Sensors that perform CDS employing 3 transistor based pixels, typically first read out and store an image frame comprising a reset level for each pixel on the sensor. Next the signal frame is captured and read out. The reset level frame stored in memory must then be subtracted from the signal frame at each pixel to provide a pixel signal level that is referenced to the pixel reset level prior to integration. This requires an extra frame of memory in the imaging system, and an extra step in the digital signal processing chain, thus adversely affecting the speed, size and cost of the system.

[0004] A typical prior art Photodiode APS pixel is shown in Figure 1. The pixel in Fig. 1 is a prior art 4 transistor pixel that comprises: a photodiode (PD); a transfer transistor (TG); floating diffusion (FD); reset transistor with a reset gate (RG); row select transistor with a row select gate, (RSG); a source follower input signal transistor (SIG); a row select signal bus (RGSB); a reset gate signal bus (RGSB), and a transfer gate signal bus (TGSB). 2 adjacent pixels are shown, each containing identical but separate transistors and row control signal busses for RG, TG and RSG. As stated above these 4 transistor pixels provide low readout noise with CDS by inclusion of an extra transistor per pixel. However the area required to implement the 4 transistor reduces the fill factor of the pixel compared to the 3 transistor pixel.

[0005] It should be readily apparent that there remains a need within the art to provide an alternate pixel architecture that has higher fill factor, and the capability to perform CDS without the need to capture and store entire frames of image data.

SUMMARY OF THE INVENTION

[0006] The present invention provides a high fill factor Photodiode Active Pixel Architecture with the capability to perform Correlated Double Sampling, (CDS). The functionality of a 4 transistor pixel is maintained while eliminating the separate row select transistor. This is done by sharing the RG control signals in one row with the row select means of an adjacent row.

ADVANTAGEOUS EFFECT OF THE INVENTION

[0007] The present invention provides a Photodiode Active Pixel sensor with true Correlated Double Sam-

piling (CDS), using only 3 transistors resulting in a higher fill factor. The advantage gained is high fill factor, and lower temporal noise. No disadvantages are foreseen.

BRIEF DESCRIPTION OF THE DRAWINGS

1300

Fig. 1 is a schematic diagram of two adjacent pixels of prior art architecture for a four transistor Photodiode Active Pixel Sensor pixel;

Fig. 2 is a schematic diagram of two adjacent pixels of a new Photodiode pixel architecture for an Active Pixel Sensor.

Fig. 3 is a timing diagram illustrating the operation of the pixels shown in Fig. 2.

Fig. 4 is a top view layout of the pixel shown in Fig. 2.

DETAILED DESCRIPTION

[0009] Fig. 2 is a schematic illustration of the 3 transistor photodiode pixel architecture for an Active Pixel Sensor (APS) as envisioned by the present invention. The preferred embodiment shown in Fig. 2 illustrates the best mode known to inventor. Other physical embodiments are realizable that are obvious variations of the embodiment shown in Fig. 2, as will be discussed further below. The pixels 10 shown in Fig. 2 are single pixels within an array of pixels having numerous rows and columns. The two row adjacent pixels 10 are shown in Fig. 2, to indicate how control the signal lines in one row are used for another purpose in an adjacent row. For the purpose of illustration of timing and operation, Fig. 2 also contains an example of per column analog signal processing used to read out the sensor. The per column signal processing referred to is the correlated double sampling that is performed under control of the Sample and Hold Signal (SHS) and Sample and Hold Reset (SHR) transistors that activate that sampling of the pixel signal voltage by the Signal Capacitor Cs and the pixel reset voltage by Reset Capacitor Cr.

[0010] As seen in Fig. 2, the pixel 10 comprises: a photodiode photodetector 12 (PD); transfer gate (TG) 23; floating diffusion (FD) 25; a reset transistor 14 with a reset gate 15 (RG); a reset drain 16 for the reset transistor 14; a source follower input signal transistor 21 (SIG); a transfer gate signal buss (TGSB) 26; and a reset gate signal buss (RGSB) 27. The row select and the row select signal buss of the prior art pixel shown in Fig. 1 is eliminated, and the row select process is accomplished in a novel manner discussed hereinbelow. As shown in Fig. 2, the reset gate signal buss (RGSB) 27 of any given row, referred to herein as Row_i, is connected to the reset drains 16 of the next row in the readout sequence, referred to herein as Row_{i+1}. The transistor, gate, and signal buss components within the

2 pixels have also been annotated with a subscript to indicate the row that they reside in.

[0011] Referring to Fig. 3, which is a timing diagram used to describe the operation of the 8 transistor pixels 10 shown in Figs. 2, the operation of the new pixel architecture for Figs. 2 will be described. It should also be understood that the pixel operation described takes place for an entire row of pixels 10 in the context of the standard per line rolling shutter operation of CMOS active pixel sensor devices. The diagram shows the timing sequence for the readout of 3 rows within the sensor; Row₁, Row₂, and Row₃. Each of the signals in the timing diagram have been annotated with a subscript indicating the row that they are associated with. It should be understood that the levels in the timing diagram are relative and can be set to be any predetermined signal level to provide optimized sensor performance.

[0012] The timing diagram begins at a point in time indicated as t_0 , where the integration time for Row_{i,1} has elapsed and the readout of Row_{i,1} commences. Row_{i,2} has been deselected, RG_{i,2} and RG_{i,1} are both high at time t_1 to reset the floating diffusions in Row_{i,1} (FD_{i,1}) to $\sim VDD$, or some other appropriate predetermined potential. The reset potential now turns on the source follower input transistors in Row_{i,1} (SFG_{i,1}), effectively selecting that row for readout of the reset level of the floating diffusion which is sampled and held on CS by pulsing SHF at time t_2 . The transfer gates for Row_{i,1} (TG_{i,1}) are pulsed on at time t_3 to transfer the signal charge from the photodiodes in Row_{i,1} onto the floating diffusions (FD_{i,1}) of Row_{i,1}. The signal levels of the floating diffusions in Row_{i,1} (FD_{i,1}) are still at a level that effectively selects Row_{i,1} for readout and the signal levels of these floating diffusions (FD_{i,1}) of Row_{i,1} are then sampled and held on CS by pulsing SGS at time t_4 . Each column in Row_{i,1} is then readout differentially through the per column difference amplifier 32 in the period indicated in the timing diagram by "Readout Row_{i,1}" at time t_5 .

[3013] Following the readout of Row_{i-1}, Row_{i-1} is deselected by pulsing RG_{i-1} on while leaving RG_{i-2} low at time t_5 . This sets the voltage of the floating diffusions for Row_{i-1} (FD_{i-1}) to a level that shuts off the source follower transistors for ROW_{i-1} (SIG_{i-1}), effectively disconnecting the source followers for ROW_{i-1} from the output signal column bus, thus deselecting Row_{i-1}. Next Row_i is selected by pulsing on RG_i while RG_{i-1} is held high at time t_5 . It should be noted that the re-pulsing of RG_{i-1} at time t_5 simply resets the floating diffusions for the previous row that was read (FD_{i-1}) to a low voltage, keeping the source follower signal transistors for that row (SIG_{i-1}) in a non-enabled state, effectively disconnecting the floating diffusions for the row that was previously read (FD_{i-1}) and prevents it from interfering with the output of the current row being read, in this case ROW_i. The reset level of the floating diffusions for ROW_i (FD_i) are sampled and held by pulsing SHR at time t_6 . TG_i is then

pulsed "high" to transfer the signal charge from the photodiodes for Row_i (Pd_i) to the floating diffusions for Row_i (FD_i) at time t_3 , and the signal level is sampled and held by pulsing SHS at time t_4 . Readout of Row_i is then completed similarly to Row_j.

[0014] This process described for Row_{i-1} and Row_i is repeated for Row_{i+1}. Row_i is deselected by setting the PD_i to a low voltage level at t_{11} by pulsing RG_i "high" while RG_{i+1} is held low disabling the source follower transistor for Row_i. Row_{i+1} is reset, which operates to select Row_{i+1} at time t_{12} because RG_i is "high" at that time and Row_{i+1} is effectively selected with all other rows deselected; the reset level is sampled and held at time t_{13} by activating SHR; the signal level is transferred from PD_{i+1} to FD_{i+1} at time t_{14} by TG_{i+1}; the signal level is then sampled and held at t_{15} ; and the Row_{i+1} readout occurs at time t_{16} as previously described.

[0015] This process repeats for all rows of the sensor until the entire frame or sequence of frame readouts is complete. It should be noted that the row select and deselect process could also be combined by eliminating the first of the 2 RG pulses and having enough overlap of the adjacent RG signals as indicated in Fig. 3. The timing illustrated by Fig. 3 is that which the inventor believes that best mode operating the invention.

[0016] From the description of operation provided it is evident that this new 3 transistor photodiode pixel architecture provides true CDS output signal without the need for storing a reset frame.

[0017] The typical prior art Photodiode APC pixel shown in Figure 1 comprised 4 transistors, and 3 row control signal busses. By comparison the new pixel architecture in Fig. 2 comprises only 3 transistors and 2 row control signal busses. The elimination of 1 transistor and buss and the associated contact regions provides more pixel area that can be allocated to the photodetector. This provides substantially higher pixel fill factor and consequently higher optical sensitivity.

[0018] Fig. 4 is a top view of the new pixel architecture as discussed above shown to further illustrate the concept of the present invention. In Fig. 4 the gate of the reset transistor in ROW_{i+1} (RG*i*+1) is the reset drain for the reset transistor of the next row to be read out in subsequent ROW_{i+1}.

(0019) Other aspects of the invention include: the invention wherein the charge-to voltage conversion node is a floating diffusion; and the invention wherein the amplifier is a source follower amplifier.

PARTS LIST

- 10 pixel
 12 photodiode
 14 reset transistor
 16 reset gate
 18 reset drain

- 21 source follower input transistor
 23 transfer gate
 25 floating diffusion
 26 transfer gate signal bus
 27 row select and photogate signal buss
 32 difference amplifier
 SHS sample and hold signal transistor
 CS signal storage capacitor
 SHR sample and hold reset transistor
 CR reset storage capacitor

• 10 •

1. An active pixel sensor having a plurality of pixels arranged in rows and columns that are read out of the active pixel sensor in a sequential order of rows with at least a plurality of the pixels comprising:

a photodiode photodetector in the row currently being read that is operatively connected to a charge to voltage conversion node; a reset transistor associated with the same pixel as the photodiode photodetector that has a source that is connected to the charge to voltage conversion node; a reset gate on the reset transistor connected to a present reset control bus and a drain on the reset transistor connected to a prior reset control bus of the row previously read; an amplifier operatively connected to the charge to voltages conversion node.

2. The invention of claim 1 wherein the source of the reset transistor is also the voltage conversion node.
 3. The invention of claim 1 wherein application of a first predetermined signal to the prior reset control bus connected to the present reset drain and, and a second predetermined signal to the present reset control bus resets the charge to voltage conversion nodes of the row presently being read.
 4. The invention of claim 3 wherein the process of resetting the charge to voltage conversion node also selects the row presently being read.
 5. The invention of claim 3 further comprising:
 - an output signal column bus for each of the columns that is operatively connected to the amplifiers for photodetectors in that column; and
 - the application of the first and second predetermined signals connects the amplifiers of the row currently being read to the output signal column bus.
 6. The invention of claim 1 wherein application of a

first predetermined signal to the prior reset control bus connected to the present reset drain and, and a second predetermined signal to the present reset control bus sets the charge to voltage conversion node to a predetermined potential that disables the amplifiers of the row previously read.

7. The invention of claim 6 wherein the process of disabling the row previously read deselects the row previously read.

8. The invention of claim 6 further comprising:

an output signal column buss for each of the columns that is operatively connected to the amplifiers for photodetectors in that column; and
the application of the first and second predetermined signals disconnects the amplifier of the row previously read from the output signal column buss.

9. A method of forming an active pixel sensor comprising the steps of:

providing a semiconductor substrate having a plurality of pixels ranged in rows and columns such that the rows can be read out sequentially; and
creating at least a portion of the pixels such that there is a present reset buss and a prior reset buss that are associated with at least one designated row within the portion and are operative in a first combination to reset the pixels in the designated row which results in selection of the designated row to be read and operative in a second combination to deselect the pixels in the designated row subsequent to the designated row being read.

10. The method of claim 9 wherein the step of creating further comprises:

creating the portion wherein each of the pixels in the designated row have an amplifier that as a first result of the first combination the amplifier is connected to a column buss; and as a second result of the second combination the pixels in the designated row do not have their amplifiers connected to the column buss.

... of the pixel cell, the row select transistors RSGI-1 and RSGI-2 are controlled by the row select gate bus for row (i-1) and row (i), respectively. The transfer transistors TGI-1 and TGI-2 are controlled by the transfer gate bus for row (i-1) and row (i), respectively. The reset transistors RGI-1 and RGI-2 are controlled by the reset gate bus for row (i-1) and row (i), respectively. The source follower input transistors SIGI-1 and SIGI-2 are controlled by the source follower input bus for row (i-1) and row (i), respectively. The column output signal bus VDD is connected to the drain of the source follower input transistors SIGI-1 and SIGI-2.

... of the pixel cell, the row select transistors RSGI-1 and RSGI-2 are controlled by the row select gate bus for row (i-1) and row (i), respectively. The transfer transistors TGI-1 and TGI-2 are controlled by the transfer gate bus for row (i-1) and row (i), respectively. The reset transistors RGI-1 and RGI-2 are controlled by the reset gate bus for row (i-1) and row (i), respectively. The source follower input transistors SIGI-1 and SIGI-2 are controlled by the source follower input bus for row (i-1) and row (i), respectively. The column output signal bus VDD is connected to the drain of the source follower input transistors SIGI-1 and SIGI-2.
